High Level Block Diagram

- The High level block diagram for this application board can be seen above. The left side of this picture shows the blocks used on the existing Lapis Development Kit. The right side of this picture shows the block used on the prototype space of the Lapis Development Kit.

Quick Start Guide

1. The jumpers should be set when we send the board, but jumpers should match the board as per the definitions in the “Hardware Board Explanations” section
2. Power the board using the a uUSB cable to Connector J11
3. Upon power-on the EEPROM will be initialized with the appropriate register map
 - Note: the RESET button can be used to re-initialize the EEPROM register map
4. When ready to connect to the different host, please disconnect the I2C pin jumpers to the Host MCU to ensure the I2C data bus is free.
5. Also, depending on the voltage level, adjust the jumper above the LDO
 - LEFT most Pins = 1.8V
 - RIGHT most Pins = 3.3V
6. Then connect the pins to the board
 - Orange = SDA
 - Yellow = SCL
 - Black = GND

EEPROM Device Address (7bit) = 0x50

IMPORTANT NOTE: This EEPROM requires a TWO BYTE register addressing scheme.

EEPROM Register Contents

Address	Reg Name	R/W	D7	D6	D5	D4	D3	D2	D1	D0	Initial Value

Hardware Board Explanation

Jumper Explanations

1. This is a selector Jumper for choosing which MCU to be programmed. For this application this is N/A since the user will not be re-programming the MCU.
 - a. J5 = Jump Pins 1 and 2
 - b. J6 = Jump Pins 1 and 2
2. This is a selector jumper to choosing how to connect the RESET pin. For this application, we want to use the RESET push button to reset the application if an EEPROM re-write is required.
 - a. J14 = Jump USB to RST
3. This is a selector jumper for choosing how to source power to this board. For this application we want to source 5V power from the uUSB connector.
 - a. J7 = Jump USB to PWR
4. This is a selector jumper for choosing the voltage level on the “POS” lines of the prototyping space and MCU source power. For this application can use either 3.3V or 5V (but tested under 3.3V condition)
 - a. J2 = Jump 3.3V to middle pin
5. This is a selector jumper for choosing the output MCU for the UART lines for either the Q111 or Q112 MCU. This function is not used in this application
 - a. Default: Connect Q112 side to middle pin for both jumpers

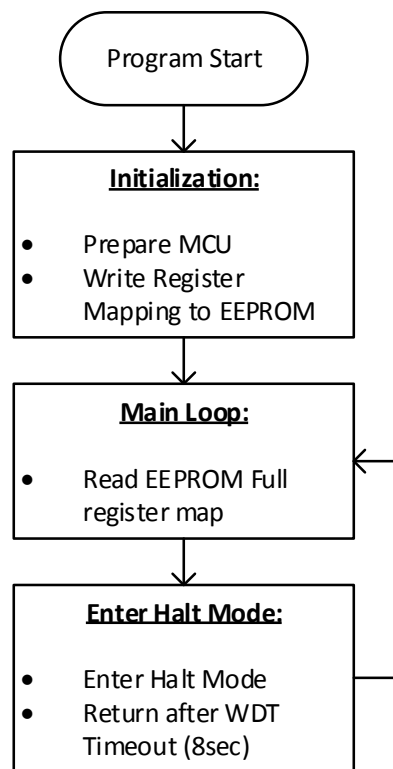

Primary Hardware Points

1. uUSB Receptacle
 - a. This serves two functions
 - i. Power the board using the USB 5V VBUS line
 - ii. Sets up a UART debug COM port on the host PC
 - b. For this application, only 5V Vbus is used
2. Reset Button for the LAPIS Q112 MCU
 - a. For this application, this will serve to re-write the EEPROM to the original settings
3. I2C Connection Jumpers
 - a. This connects the I2C bus lines to the onboard LAPIS Q112 MCU.
 - b. When connecting to an external host, these should not be jumped
 - c. When resetting the EEPROM memory map, this should be jumped
4. On-Board Power Selector
 - a. This connector allows the user to select the voltage rail of the EEPROM.
 - i. Jump Left = 1.8V
 - ii. Jump Right = 3.3V
5. External Jumpers for I2C Connection
 - a. Orange = SDA
 - b. Yellow = SCL
6. External Jumper for GND

Firmware Flow Chart

High Level Flowchart of Operation

- The Purpose of the MCU on this board is to complete only 1 task: to write the default register mapping to the EEPROM device.
- In the main loop, the EEPROM is read to check the register contents, but ultimately is not helpful to the end user.

EEPROM Register Content Confirmation

In order to ensure the EEPROM is working as specified, we confirmed operation of this device using two methods.

Method 1: Checking the EEPROM using the on-board I2C Reads

The screenshot shows a debugger window titled 'main.c'. The left pane displays a list of lines with their corresponding BP (Breakpoint) and Address. A red square indicates a breakpoint is set at line 00233, address 0:0B1AH. The right pane shows the source code of the program. The code includes preprocessor directives for escape sequences, a main function with initialization, a loop that reads from an I2C device and stores the result in 'Test00_Return', and a static void initialization function for peripherals.

```

Line BP Address
00209 #define ESC_NEWLINE      "\n\r"
00210 #define ESC_PREVLINE    "\033[F"
00211 #define ESC_ERASE2END   "\033[J"
00212
00213 //=====
00214 //      Start of MAIN FUNCTION
00215 //=====
00216 int main(void)
00217 {
00218     Initialization(); //Ports, UART, Timers, Oscillator, Comparators, etc.
00219     #ifdef DebugOn
00220     PRINTF("Start Program");
00221     #endif
00222     I2C_Write(BR24_I2C_ADDR, &BR24_REG00, 2, &BR24_REG00_Contents, 255);
00223
00224     MainLoop:
00225     main_clrWDT();
00226
00227     I2C_Read(BR24_I2C_ADDR, &BR24_REG00, 2, &Test00_Return, 255);
00228
00229     HLT = 1;          //Wait time here depends on the WDT timing
00230     __asm("nop\n");
00231     __asm("nop\n");
00232
00233     goto MainLoop;
00234 }
00235 //=====
00236 //      End of MAIN FUNCTION
00237 //=====
00238
00239
00240 //=====
00241 //      Start of Other Functions...
00242 //=====
00243
00244 //      Initialize Micro to Desired State...
00245 //=====
00246 static void Initialization(void){
00247
00248     //Initialize Peripherals
00249     //BLKCON2 Control Bits...Manually Set 4/12/2013
00250     DSIO0 = 1; // 0=> Enables Synchronous Serial Port 0 (initial value).
00251     #ifdef DebugOn
00252     DUA0 = 0; // 0=> Enables the operation of UART0 (initial value).
00253     #endif
00254     #ifndef DebugOn
00255     DUA0 = 1; // 0=> Enables the operation of UART0 (initial value).
00256     #endif
00257     DUA1 = 1; // 0=> Enables Uart1 (initial value).

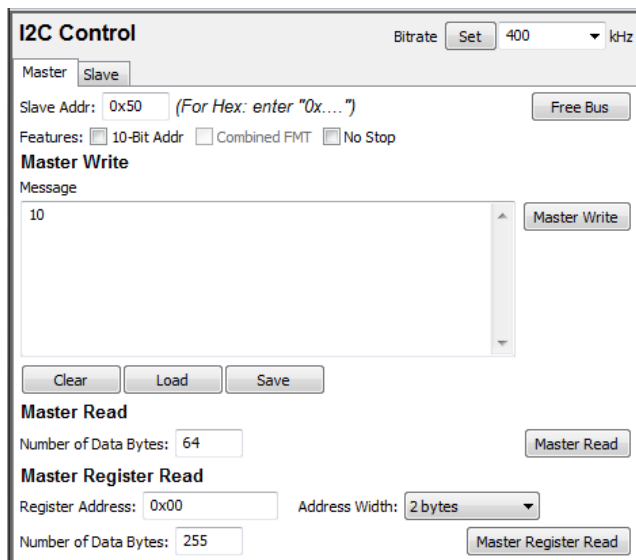

```

In the above picture, we have setup a breakpoint after the MCU goes into Halt Mode. Thus, at this point, the MCU has written and re-read the register contents of the EEPROM. The Contents are then placed in the character array "Test00_Return". Upon checking this variable in the debugger, we can see that the register values were taken successfully

Method 2: Checking the EEPROM using an Aardvark

In the below picture, the Total Phase Aardvark I2C tool was used to confirm the operation of this device

After Performing the full register map read, we can see that the contents are loaded successfully.
